Introduction to MDP

 Markov decision processes formally describe an environment for reinforcement learning

- Where the environment is fully observable
- i.e. The current state completely characterises the process
- Preliminary from probability theorem:
 - For a function f of random variable x, the expectation is defined as

$$\mathbb{E}[f(x)] = \sum_{x} P(x)f(x)$$

Markov Property

"The future is independent of the past given the present"

Definition

A state S_t is Markov if and only if

$$\mathbb{P}\left[S_{t+1}\mid S_{t}
ight] = \mathbb{P}\left[S_{t+1}\mid S_{1},...,S_{t}
ight]$$

- The state captures all relevant information from the history
- Once the state is known, the history may be thrown away
- i.e. The state is a sufficient statistic of the future

State Transition Matrix

For a Markov state s and successor state s', the state transition probability is defined by

$$\mathcal{P}_{ss'} = \mathbb{P}\left[S_{t+1} = s' \mid S_t = s
ight]$$

State transition matrix \mathcal{P} defines transition probabilities from all states s to all successor states s',

$$\mathcal{P} = \textit{from} egin{bmatrix} \textit{to} \\ \mathcal{P}_{11} & \dots & \mathcal{P}_{1n} \\ \vdots & & \\ \mathcal{P}_{n1} & \dots & \mathcal{P}_{nn} \end{bmatrix}$$

where each row of the matrix sums to 1.

A Markov process is a memoryless random process, i.e. a sequence of random states $S_1, S_2, ...$ with the Markov property.

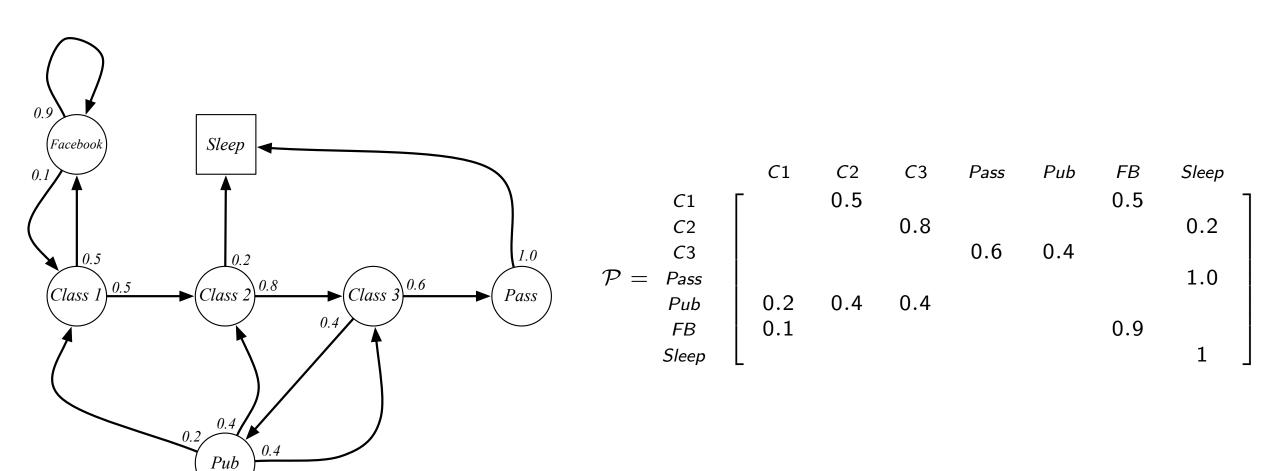

Definition

A Markov Process (or Markov Chain) is a tuple $\langle \mathcal{S}, \mathcal{P} \rangle$

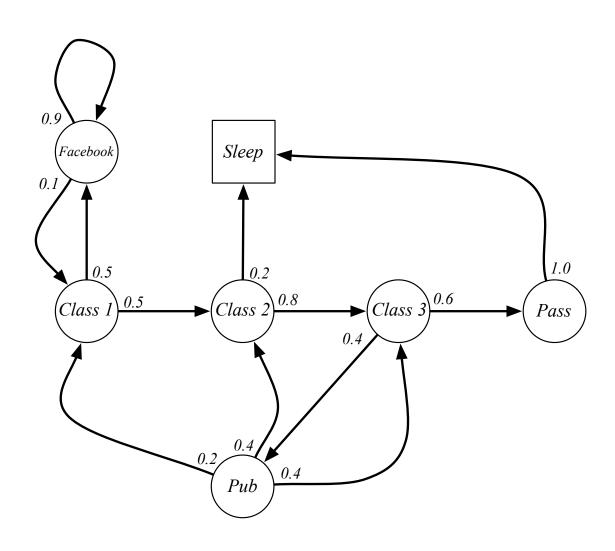

- lacksquare \mathcal{S} is a (finite) set of states
- lacksquare is a state transition probability matrix,

$$\mathcal{P}_{ss'} = \mathbb{P}\left[S_{t+1} = s' \mid S_t = s\right]$$

Student Markov Chain

Student Markov Chain Episodes

Sample episodes for Student Markov Chain starting from $S_1 = C1$

$$S_1, S_2, ..., S_T$$

Markov Reward Process

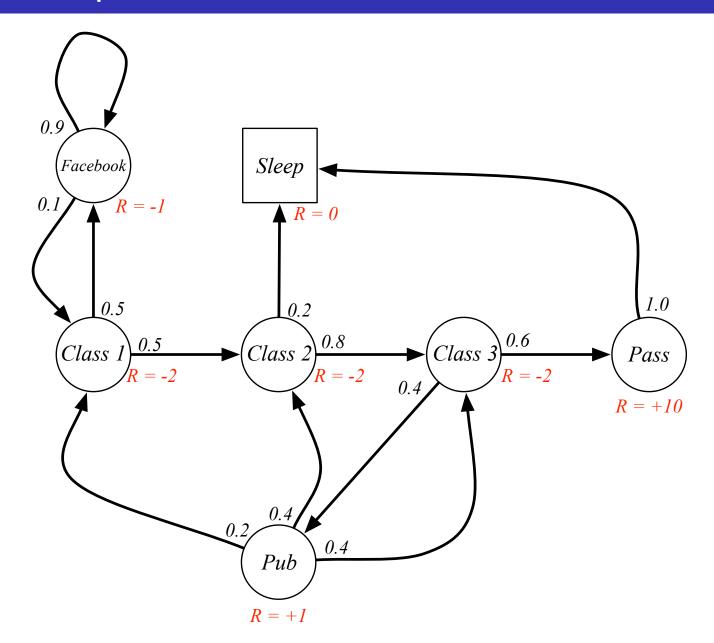

An MRP is a Markov chain with reward values.

Definition

A Markov Reward Process is a tuple $\langle \mathcal{S}, \mathcal{P}, \mathcal{R}, \gamma \rangle$

- lacksquare \mathcal{S} is a finite set of states
- \mathcal{P} is a state transition probability matrix, $\mathcal{P}_{ss'} = \mathbb{P}\left[S_{t+1} = s' \mid S_t = s\right]$
- lacksquare R is a reward function, $\mathcal{R}_s = \mathbb{E}\left[R_{t+1} \mid S_t = s\right]$
- lacksquare γ is a discount factor, $\gamma \in [0,1]$

Example: Student MRP

Return

Definition

The return G_t is the total discounted reward from time-step t.

$$G_t = R_{t+1} + \gamma R_{t+2} + \dots = \sum_{k=0}^{\infty} \gamma^k R_{t+k+1}$$

- The discount $\gamma \in [0,1]$ is the present value of future rewards
- The value of receiving reward R after k+1 time-steps is $\gamma^k R$.
- This values immediate reward above delayed reward.
 - lacksquare γ close to 0 leads to "myopic" evaluation
 - lacksquare γ close to 1 leads to "far-sighted" evaluation

Why discount?

Most Markov reward and decision processes are discounted. Why?

- Mathematically convenient to discount rewards
- Avoids infinite returns in cyclic Markov processes
- Uncertainty about the future may not be fully represented
- If the reward is financial, immediate rewards may earn more interest than delayed rewards
- Animal/human behaviour shows preference for immediate reward
- It is sometimes possible to use *undiscounted* Markov reward processes (i.e. $\gamma = 1$), e.g. if all sequences terminate.

Value Function

• The value function v(s) gives the long-term value of state s

Definition

The state value function v(s) of an MRP is the expected return starting from state s

$$v(s) = \mathbb{E}\left[G_t \mid S_t = s\right]$$

Student MRP return

Sample returns for Student MRP: Starting from $S_1 = C1$ with $\gamma = \frac{1}{2}$

$$G_1 = R_2 + \gamma R_3 + \dots + \gamma^{T-2} R_T$$

$$v_{1} = -2 - 2 * \frac{1}{2} - 2 * \frac{1}{4} + 10 * \frac{1}{8} = -2.25$$

$$v_{1} = -2 - 1 * \frac{1}{2} - 1 * \frac{1}{4} - 2 * \frac{1}{8} - 2 * \frac{1}{16} = -3.125$$

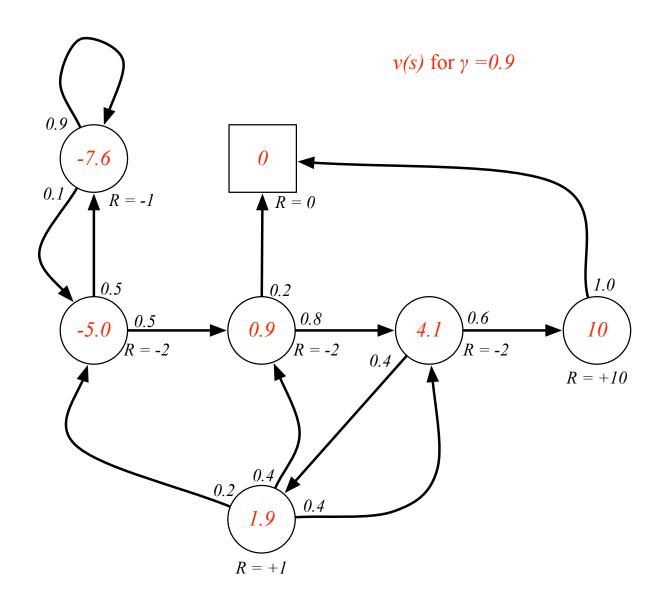

$$v_{1} = -2 - 2 * \frac{1}{2} - 2 * \frac{1}{4} + 1 * \frac{1}{8} - 2 * \frac{1}{16} \dots = -3.41$$

$$v_{1} = -2 - 1 * \frac{1}{2} - 1 * \frac{1}{4} - 2 * \frac{1}{8} - 2 * \frac{1}{16} \dots = -3.20$$

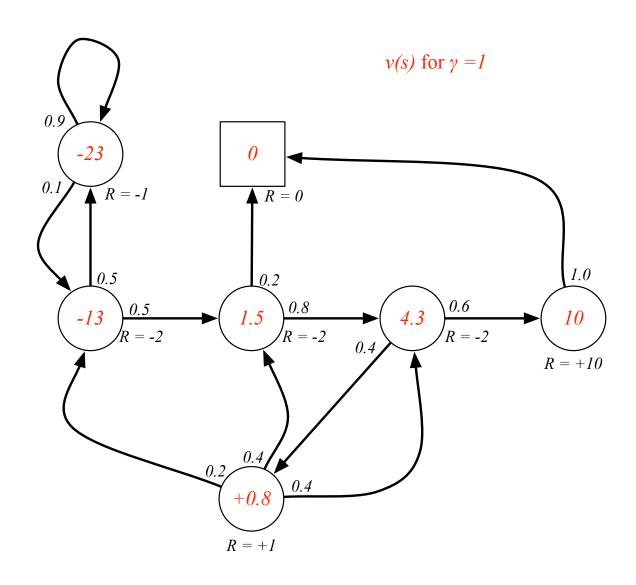

State Value Function for Student MRP (i)

State Value Function for Student MRP (ii)

State Value Function for Student MRP (iii)

Bellman Equations for MRPs (i)

The value function can be decomposed into two parts:

- \blacksquare immediate reward R_{t+1}
- discounted value of successor state $\gamma v(S_{t+1})$

$$v(s) = \mathbb{E} [G_t \mid S_t = s]$$

$$= \mathbb{E} [R_{t+1} + \gamma R_{t+2} + \gamma^2 R_{t+3} + ... \mid S_t = s]$$

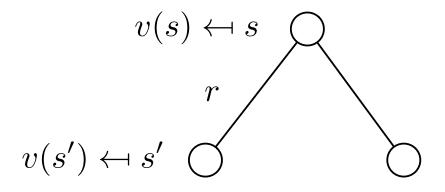

$$= \mathbb{E} [R_{t+1} + \gamma (R_{t+2} + \gamma R_{t+3} + ...) \mid S_t = s]$$

$$= \mathbb{E} [R_{t+1} + \gamma G_{t+1} \mid S_t = s]$$

$$= \mathbb{E} [R_{t+1} + \gamma V(S_{t+1}) \mid S_t = s]$$

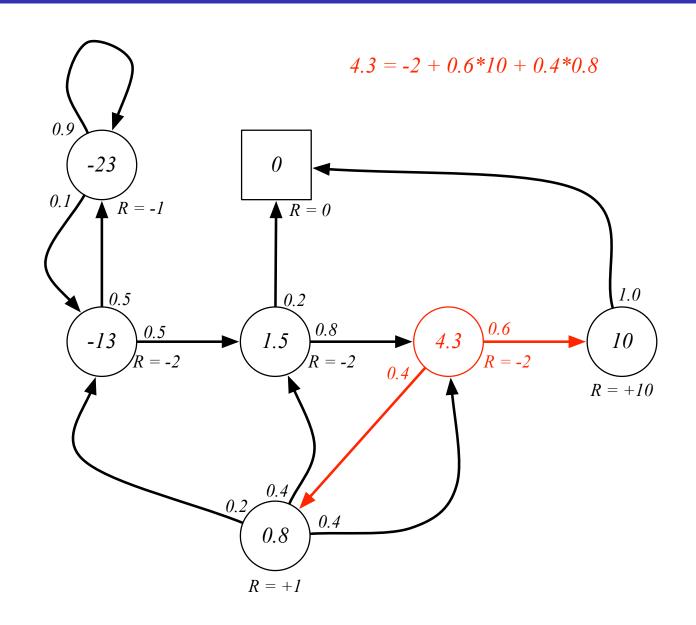

Bellman Equations for MRPs (ii)

$$v(s) = \mathbb{E}\left[R_{t+1} + \gamma v(S_{t+1}) \mid S_t = s\right]$$

$$v(s) = \mathcal{R}_s + \gamma \sum_{s' \in \mathcal{S}} \mathcal{P}_{ss'} v(s')$$

Example: Bellman equation for student MRP

Bellman equation in matrix form

The Bellman equation can be expressed concisely using matrices,

$$\mathbf{v} = \mathcal{R} + \gamma \mathcal{P} \mathbf{v}$$

where v is a column vector with one entry per state

$$\begin{bmatrix} v(1) \\ \vdots \\ v(n) \end{bmatrix} = \begin{bmatrix} \mathcal{R}_1 \\ \vdots \\ \mathcal{R}_n \end{bmatrix} + \gamma \begin{bmatrix} \mathcal{P}_{11} & \dots & \mathcal{P}_{1n} \\ \vdots & & & \\ \mathcal{P}_{11} & \dots & \mathcal{P}_{nn} \end{bmatrix} \begin{bmatrix} v(1) \\ \vdots \\ v(n) \end{bmatrix}$$

Solving Bellman's Equation

- The Bellman equation is a linear equation
- It can be solved directly:

$$v = \mathcal{R} + \gamma \mathcal{P} v$$
 $(I - \gamma \mathcal{P}) v = \mathcal{R}$
 $v = (I - \gamma \mathcal{P})^{-1} \mathcal{R}$

- Computational complexity is $O(n^3)$ for n states
- Direct solution only possible for small MRPs
- There are many iterative methods for large MRPs, e.g.
 - Dynamic programming
 - Monte-Carlo evaluation
 - Temporal-Difference learning

Markov Decision Process

A Markov decision process (MDP) is a Markov reward process with decisions. It is an *environment* in which all states are Markov.

Definition

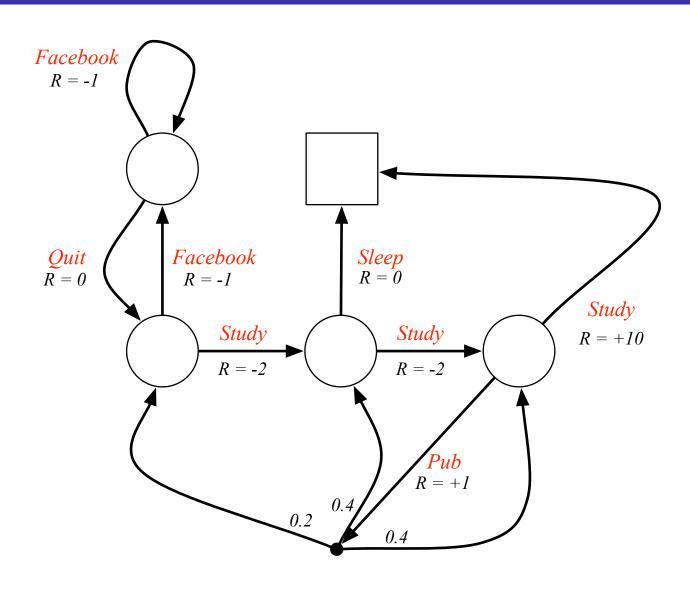

A Markov Decision Process is a tuple $\langle S, A, P, R, \gamma \rangle$

- lacksquare S is a finite set of states
- lacksquare \mathcal{A} is a finite set of actions
- lacksquare is a state transition probability matrix,

$$\mathcal{P}_{ss'}^{a} = \mathbb{P}\left[S_{t+1} = s' \mid S_t = s, A_t = a\right]$$

- lacksquare R is a reward function, $\mathcal{R}_s^a = \mathbb{E}\left[R_{t+1} \mid S_t = s, A_t = a\right]$
- lacksquare γ is a discount factor $\gamma \in [0, 1]$.

Example: Student MDP

Policy

Definition

A policy π is a distribution over actions given states,

$$\pi(a|s) = \mathbb{P}\left[A_t = a \mid S_t = s\right]$$

- A policy fully defines the behaviour of an agent
- MDP policies depend on the current state (not the history)
- i.e. Policies are *stationary* (time-independent), $A_t \sim \pi(\cdot|S_t), \forall t > 0$

Reducing MDP to MRP

- Given an MDP $\mathcal{M} = \langle \mathcal{S}, \mathcal{A}, \mathcal{P}, \mathcal{R}, \gamma \rangle$ and a policy π
- The state sequence $S_1, S_2, ...$ is a Markov process $\langle S, \mathcal{P}^{\pi} \rangle$
- The state and reward sequence $S_1, R_2, S_2, ...$ is a Markov reward process $\langle S, \mathcal{P}^{\pi}, \mathcal{R}^{\pi}, \gamma \rangle$
- where

$$\mathcal{P}^{\pi}_{s,s'} = \sum_{a \in \mathcal{A}} \pi(a|s) \mathcal{P}^{a}_{ss'}$$
 $\mathcal{R}^{\pi}_{s} = \sum_{a \in \mathcal{A}} \pi(a|s) \mathcal{R}^{a}_{s}$

Conclusions

- MRP assumes that the reward at each state is a Markov process
- The value function describes the return in MRP
- Bellman equations for small MRPs can be solved linearly.
- MDP is the formal description of the environment for RL, when the observation is complete.
- MDP is defined by the Markov process, generalizing the MRP with actions taken by the agent.
- In the next lecture, we will generalize the Bellman equations for MDPs.
